4.4 Assessing Requirements

Return to Requirements

An important part of having functional and non-functional requirements is access a particular effort to determine if the effort complies with the requirements. The approach is slightly different between Functional and non-functional requirements.

For Functional Requirements, it is important to think about what requirements need to be covered for a particular effort. For example, which Networks need to be supported? (Wired Network, Wireless Network. Bluetooth, ZigBee, Near-Field-Communication (NFC), etc).

For Non-functional Requirements often have a large impact on the components that are selected as part of the infrastructure. For example, if a component is not Scalability, then it becomes product that is build using that product is probably not scalable.

The following sections are meant as aids in helping evaluate a project Functional and Non-FUnctional Requirements.

- 1_functional
- 4.4.2 Non-functional Requirements Assessment
