

Message Broker

[Return to Glossary](#)

Message Broker is an intermediary program that translates a system's language from one internationally suitable language to another via a telecommunication medium.

In telecommunication networks, programs interact by exchanging messages that are formally defined, i.e., by means of the act of messaging. In these networks, a message broker serves as an intermediary program, which translates a message from the sender's formal messaging protocol to the receiver's formal messaging protocol.

A message broker is also known as an integration broker or [middleware](#).
